## Advanced Semantics (ASM)

### Final Exam, January 2020

Khalil Ghorbal and Alan Schmitt

## 1 Operational Semantics

Recall that the *call by value* strategy evaluates the arguments of a function before passing them to the function. Using such strategy

1. Give a big-step semantics for the  $\lambda$ -calculus
2. Give a small-step semantics for the  $\lambda$ -calculus
3. Give a reduction strategy for the  $\lambda$ -calculus
4. Give an abstract machine semantics for the  $\lambda$ -calculus
5. Select any two semantics from 1. to 4. above and show their equivalence

## 2 Categorical Semantics

### A. Monadic Semantics

1. Suppose you have a 'let' binder in your language, that is 'let  $x = t$  in  $u$ ' is a term ( $x$  is a variable and  $t, u$  are terms). Is it possible to give a general big-step operational semantics for such binder without discussing the possible reduction of the term  $u$  once the variable  $x$  is substituted by  $t$ ? Explain.
2. Recall what a Kleisli triple is and describe concisely how does it capture the semantics of a particular computation.
3. Explain why and how types are used in a Kleisli triple and give the semantics of the let binder with respect to a given computation.

### B. Category Theory: Pullbacks

A commutative diagram of a category  $\mathcal{C}$

$$\begin{array}{ccc} P & \xrightarrow{p_1} & X \\ p_2 \downarrow & & \downarrow f \\ Y & \xrightarrow{g} & Z \end{array}$$

is called a *pullback* diagram (*produit fibré* dans la langue de Molière) when the following property holds: for every commutative diagram

$$\begin{array}{ccc} T & \xrightarrow{q_1} & X \\ q_2 \searrow & & \downarrow f \\ & Y & \xrightarrow{g} Z \end{array}$$

there exists a unique morphism  $h : T \rightarrow P$  such that the following diagram commutes.

- Given  $f : X \rightarrow Z$  and  $g : Y \rightarrow Z$ , give explicitly a pullback in the category of sets (objects are sets and morphisms are functions).
- Given two pullback diagrams

show that we can construct another pullback by gluing together the given pullbacks:

- A morphism  $m : A \rightarrow B$  in  $\mathcal{C}$  is a *monomorphism* (or mono) if we can remove it from the left for every pair of morphisms  $f, g : X \rightarrow A$ , that is

$$m \circ f = m \circ g \implies f = g .$$

Show that monomorphisms correspond to injective functions in the category of sets.

- Similarly, a morphism  $e : A \rightarrow B$  in  $\mathcal{C}$  is an *epimorphism* (or epi) if we can remove it from the right for pair of morphisms  $f, g : B \rightarrow Y$ , that is

$$f \circ e = g \circ e \implies f = g .$$

Show that epimorphisms correspond to surjective functions in the category of sets.

- Show that a morphism  $m$  is mono if and only if the following commutative diagram is a pullback.

What is the meaning of this property in the category of sets?

- Show that every pullback diagram

satisfies  $m : A \rightarrow Y$  and  $m' : X \rightarrow Z$  are mono. Does the converse hold? Can you think of a counter-example in the category of sets?
